Chapter 4

Threads

Eighth Edition
By William Stallings
Processes and Threads

Resource Ownership

Process includes a virtual address space to hold the process image
- the OS performs a protection function to prevent unwanted interference between processes with respect to resources

Scheduling/Execution

Follows an execution path that may be interleaved with other processes
- a process has an execution state (Running, Ready, etc.) and a dispatching priority and is scheduled and dispatched by the OS
Processes and Threads

- The unit of dispatching is referred to as a *thread* or *lightweight process*

- The unit of resource ownership is referred to as a *process* or *task*

- **Multithreading** - The ability of an OS to support multiple, concurrent paths of execution within a single process
A single thread of execution per process, in which the concept of a thread is not recognized, is referred to as a single-threaded approach.

MS-DOS is an example.
Multithreaded Approaches

- The right half of Figure 4.1 depicts multithreaded approaches.

- A Java run-time environment is an example of a system of one process with multiple threads.

Figure 4.1  Threads and Processes
Processes

- The unit or resource allocation and a unit of protection
- A virtual address space that holds the process image
- Protected access to:
  - processors
  - other processes
  - files
  - I/O resources
One or More Threads in a Process

Each thread has:

• an execution state (Running, Ready, etc.)
• saved thread context when not running
• an execution stack
• some per-thread static storage for local variables
• access to the memory and resources of its process (all threads of a process share this)
Figure 4.2   Single Threaded and Multithreaded Process Models
Benefits of Threads

- Takes less time to create a new thread than a process
- Less time to terminate a thread than a process
- Switching between two threads takes less time than switching between processes
- Threads enhance efficiency in communication between programs
Thread Use in a Single-User System

- Foreground and background work
- Asynchronous processing
- Speed of execution
- Modular program structure
In an OS that supports threads, scheduling and dispatching is done on a thread basis.

Most of the state information dealing with execution is maintained in thread-level data structures:

- Suspending a process involves suspending all threads of the process.
- Termination of a process terminates all threads within the process.
The key states for a thread are:

- Running
- Ready
- Blocked

Thread operations associated with a change in thread state are:

- Spawn
- Block
- Unblock
- Finish
Figure 4.3  Remote Procedure Call (RPC) Using Threads

(a) RPC Using Single Thread

(b) RPC Using One Thread per Server (on a uniprocessor)
Figure 4.4  Multithreading Example on a Uniprocessor
It is necessary to synchronize the activities of the various threads

- all threads of a process share the same address space and other resources
- any alteration of a resource by one thread affects the other threads in the same process
Types of Threads

User Level Thread (ULT)

Kernel level Thread (KLT)
User-Level Threads (ULTs)

- All thread management is done by the application.
- The kernel is not aware of the existence of threads.

(a) Pure user-level
Figure 4.6 Examples of the Relationships Between User-Level Thread States and Process States

Colored state is current state.
Thread switching does not require kernel mode privileges

Scheduling can be application specific

ULTs can run on any OS
Disadvantages of ULTs

- In a typical OS many system calls are blocking
  - as a result, when a ULT executes a system call, not only is that thread blocked, but all of the threads within the process are blocked

- In a pure ULT strategy, a multithreaded application cannot take advantage of multiprocessing
Overcoming ULT Disadvantages

Jacketing

- converts a blocking system call into a non-blocking system call

Writing an application as multiple processes rather than multiple threads
Kernel-Level Threads (KLTs)

- Thread management is done by the kernel
- no thread management is done by the application
- Windows is an example of this approach

(b) Pure kernel-level
Advantages of KLTs

- The kernel can simultaneously schedule multiple threads from the same process on multiple processors.
- If one thread in a process is blocked, the kernel can schedule another thread of the same process.
- Kernel routines can be multithreaded.
## Disadvantage of KLTs

The transfer of control from one thread to another within the same process requires a mode switch to the kernel.

<td>1,840</td>
</tr>
</tbody>
</table>

Table 4.1
Thread and Process Operation Latencies (μs)
Combined Approaches

- Thread creation is done in the user space
- Bulk of scheduling and synchronization of threads is by the application
- Solaris is an example
<table>
<thead>
<tr>
<th>Threads:Processes</th>
<th>Description</th>
<th>Example Systems</th>
</tr>
</thead>
<tbody>
<tr>
<td>1:1</td>
<td>Each thread of execution is a unique process with its own address space and resources.</td>
<td>Traditional UNIX implementations</td>
</tr>
<tr>
<td>M:1</td>
<td>A process defines an address space and dynamic resource ownership. Multiple threads may be created and executed within that process.</td>
<td>Windows NT, Solaris, Linux, OS/2, OS/390, MACH</td>
</tr>
<tr>
<td>1:M</td>
<td>A thread may migrate from one process environment to another. This allows a thread to be easily moved among distinct systems.</td>
<td>Ra (Clouds), Emerald</td>
</tr>
<tr>

Relationship between Threads and Processes
Figure 4.7 Performance Effect of Multiple Cores

(a) Speedup with 0%, 2%, 5%, and 10% sequential portions

(b) Speedup with overheads
Figure 4.8 Scaling of Database Workloads on Multiple-Processor Hardware
Applications That Benefit

- Multithreaded native applications
  - characterized by having a small number of highly threaded processes

- Multiprocess applications
  - characterized by the presence of many single-threaded processes

- Java applications

- Multiinstance applications
  - multiple instances of the application in parallel
Valve Game Software

Figure 4.9  Hybrid Threading for Rendering Module
Windows 8 Process and Thread Management

- An **application** consists of one or more processes
- Each **process** provides the resources needed to execute a program
- A **thread** is the entity within a process that can be scheduled for execution
- A **job object** allows groups of process to be managed as a unit
- A **thread pool** is a collection of worker threads that efficiently execute asynchronous callbacks on behalf of the application
- A **fiber** is a unit of execution that must be manually scheduled by the application
- **User-mode scheduling (UMS)** is a lightweight mechanism that applications can use to schedule their own threads
Changes in Windows 8

- Changes the traditional Windows approach to managing background tasks and application lifecycles
- Developers are now responsible for managing the state of their individual applications
- In the new Metro interface Windows 8 takes over the process lifecycle of an application
  - a limited number of applications can run alongside the main app in the Metro UI using the SnapView functionality
  - only one Store application can run at one time
- Live Tiles give the appearance of applications constantly running on the system
  - in reality they receive push notifications and do not use system resources to display the dynamic content offered
Metro Interface

- Foreground application in the Metro interface has access to all of the processor, network, and disk resources available to the user
  - all other apps are suspended and have no access to these resources

- When an app enters a suspended mode, an event should be triggered to store the state of the user’s information
  - this is the responsibility of the application developer

- Windows 8 may terminate a background app
  - you need to save your app’s state when it’s suspended, in case Windows terminates it so that you can restore its state later
  - when the app returns to the foreground another event is triggered to obtain the user state from memory
Processes and services provided by the Windows Kernel are relatively simple and general purpose

• implemented as objects
• created as new process or a copy of an existing
• an executable process may contain one or more threads
• both processes and thread objects have built-in synchronization capabilities
Figure 4.10  A Windows Process and Its Resources
Windows makes use of two types of process-related objects:

<table>
<thead>
<tr>
<th>Processes</th>
<th>Threads</th>
</tr>
</thead>
<tbody>
<tr>
<td>• an entity corresponding to a user job or application that owns resources</td>
<td>• a dispatchable unit of work that executes sequentially and is interruptible</td>
</tr>
<tr>
<td>Process ID</td>
<td>A unique value that identifies the process to the operating system.</td>
</tr>
<tr>
<td>--------------------</td>
<td>---------------------------------------------------------------------</td>
</tr>
<tr>
<td>Security descriptor</td>
<td>Describes who created an object, who can gain access to or use the object, and who is denied access to the object.</td>
</tr>
<tr>
<td>Base priority</td>
<td>A baseline execution priority for the process's threads.</td>
</tr>
<tr>
<td>Default processor affinity</td>
<td>The default set of processors on which the process's threads can run.</td>
</tr>
<tr>
<td>Quota limits</td>
<td>The maximum amount of paged and nonpaged system memory, paging file space, and processor time a user's processes can use.</td>
</tr>
<tr>
<td>Execution time</td>
<td>The total amount of time all threads in the process have executed.</td>
</tr>
<tr>
<td>I/O counters</td>
<td>Variables that record the number and type of I/O operations that the process's threads have performed.</td>
</tr>
<tr>
<td>VM operation counters</td>
<td>Variables that record the number and types of virtual memory operations that the process's threads have performed.</td>
</tr>
<tr>
<td>Exception/debugging ports</td>
<td>Interprocess communication channels to which the process manager sends a message when one of the process's threads causes an exception. Normally, these are connected to environment subsystem and debugger processes, respectively.</td>
</tr>
<tr>
<td>Exit status</td>
<td>The reason for a process's termination.</td>
</tr>
</tbody>
</table>

Table 4.3 Windows Process Object Attributes (Table is on page 175 in textbook)
<table>
<thead>
<tr>
<th>Thread ID</th>
<th>A unique value that identifies a thread when it calls a server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thread context</td>
<td>The set of register values and other volatile data that defines the execution state of a thread.</td>
</tr>
<tr>
<td>Dynamic priority</td>
<td>The thread's execution priority at any given moment.</td>
</tr>
<tr>
<td>Base priority</td>
<td>The lower limit of the thread's dynamic priority.</td>
</tr>
<tr>
<td>Thread processor affinity</td>
<td>The set of processors on which the thread can run, which is a subset or all of the processor affinity of the thread's process.</td>
</tr>
<tr>
<td>Thread execution time</td>
<td>The cumulative amount of time a thread has executed in user mode and in kernel mode.</td>
</tr>
<tr>
<td>Alert status</td>
<td>A flag that indicates whether a waiting thread may execute an asynchronous procedure call.</td>
</tr>
<tr>
<td>Suspension count</td>
<td>The number of times the thread's execution has been suspended without being resumed.</td>
</tr>
<tr>
<td>Impersonation token</td>
<td>A temporary access token allowing a thread to perform operations on behalf of another process (used by subsystems).</td>
</tr>
<tr>
<td>Termination port</td>
<td>An interprocess communication channel to which the process manager sends a message when the thread terminates (used by subsystems).</td>
</tr>
<tr>
<td>Thread exit status</td>
<td>The reason for a thread's termination.</td>
</tr>
</tbody>
</table>

**Windows**

**Thread Object Attributes**

(Table is on page 175 in textbook)
Multithreaded Process

Achieves concurrency without the overhead of using multiple processes

Threads within the same process can exchange information through their common address space and have access to the shared resources of the process.

Threads in different processes can exchange information through shared memory that has been set up between the two processes.

Figure 4.11  Windows Thread States
Solaris Process

It makes use of four thread-related concepts:

<table>
<thead>
<tr>
<th>Process</th>
<th>• includes the user’s address space, stack, and process control block</th>
</tr>
</thead>
<tbody>
<tr>
<td>User-level Threads</td>
<td>• a user-created unit of execution within a process</td>
</tr>
<tr>
<td>Lightweight Processes (LWP)</td>
<td>• a mapping between ULTs and kernel threads</td>
</tr>
<tr>
<td>Kernel Threads</td>
<td>• fundamental entities that can be scheduled and dispatched to run on one of the system processors</td>
</tr>
</tbody>
</table>
Figure 4.12 Processes and Threads in Solaris

Syscall()
Figure 4.13  Process Structure in Traditional UNIX and Solaris [LEWI96]
A Lightweight Process (LWP) Data Structure Includes:

- An LWP identifier
- The priority of this LWP
- A signal mask
- Saved values of user-level registers
- The kernel stack for this LWP
- Resource usage and profiling data
- Pointer to the corresponding kernel thread
- Pointer to the process structure
Figure 4.14  Solaris Thread States
Most operating systems contain two fundamental forms of concurrent activity:

**Processes (threads)** cooperate with each other and manage the use of shared data structures by primitives that enforce mutual exclusion and synchronize their execution.

**Interrupts** synchronized by preventing their handling for a period of time.
Solaris Solution

- Solaris employs a set of kernel threads to handle interrupts
  - an interrupt thread has its own identifier, priority, context, and stack
  - the kernel controls access to data structures and synchronizes among interrupt threads using mutual exclusion primitives
  - interrupt threads are assigned higher priorities than all other types of kernel threads
A process, or task, in Linux is represented by a task_struct data structure.

This structure contains information in a number of categories.
Figure 4.15  Linux Process/Thread Model
Linux does not recognize a distinction between threads and processes.

A new process is created by copying the attributes of the current process.

User-level threads are mapped into kernel-level processes.

The new process can be cloned so that it shares resources.

The clone() call creates separate stack spaces for each process.
Linux Namespaces

- A namespace enables a process to have a different view of the system than other processes that have other associated namespaces.

- One of the overall goals is to support the implementation of control groups, cgroups), a tool for lightweight virtualization that provides a process or group of processes with the illusion that they are the only processes on the system.

- There are currently six namespaces in Linux:
  - mnt
  - pid
  - net
  - ipc
  - uts
  - user
An Android application is the software that implements an app.

Each Android application consists of one or more instances of one or more of four types of application components.

Each component performs a distinct role in the overall application and even by other applications.

Four types of components:
- Activities
- Services
- Content providers
- Broadcast receivers
Dedicated Process

Broadcast Receiver

Content Provider

Activity

Service

Dedicated Virtual Machine

Figure 4.16 Android Application
Figure 4.17 Activity State Transition Diagram

Apps with higher priority need memory when user navigates to the activity.

User returns to the activity when:
- The activity is resumed.
- The activity is paused.
- The activity is stopped.
- The activity is destroyed.

User navigates to the activity when:
- The app process is killed.
- The activity is paused.
- The activity is stopped.

Activity launched
onCreate()

Entire Lifetime
onStart()

Visible Lifetime
onResume()

Foreground Lifetime
onPause()

Paused
onStop()

Stopped
onDestroy()

Activity shut down
Processes and Threads

- A precedence hierarchy is used to determine which process or processes to kill in order to reclaim needed resources.

- Processes are killed beginning with the lowest precedence first.

- The levels of the hierarchy, in descending order of precedence are:
  - Foreground process
  - Visible process
  - Service process
  - Background process
  - Empty process
Mac OS X Grand Central Dispatch (GCD)

- Provides a pool of available threads
- Designers can designate portions of applications, called *blocks*, that can be dispatched independently and run concurrently
- Concurrency is based on the number of cores available and the thread capacity of the system
A simple extension to a language
A block defines a self-contained unit of work
Enables the programmer to encapsulate complex functions
Scheduled and dispatched by queues
Dispatched on a first-in-first-out basis
Can be associated with an event source, such as a timer, network socket, or file descriptor
Summary

- Processes and threads
  - Multithreading
  - Thread functionality
- Types of threads
  - User level and kernel level threads
- Multicore and multithreading
